

PLANT MEDICINAL USE AND LEXICAL VARIATION WITHIN THE FOLK
CLASSIFICATION SYSTEM OF THE HIGHLAND MAYA OF CHIAPAS, MEXICO

by

ILYSSA FAITH BERG

(Under the Direction of Brent Berlin)

ABSTRACT

In any local ethnobotanical system of classification, a considerable amount of variation exists in the names given for a plant species, even for a sample of knowledgeable informants. The variation is not applied consistently across the sample of plants and therefore can be productively analyzed in order to understand the patterns within the variation. This thesis examines the extent of variation in lexical and medicinal use responses both within and between two closely related Mayan languages, Tzeltal and Tzotzil. The relationship between medicinal plant use and naming diversity is described and tested for three data groups – Tzeltal, Tzotzil, and the pooled data. The results suggest a weak trend that the more agreement there is regarding a plant species' medicinal use, the less the diversity of naming, both within and between closely related language groups.

CHAPTER 1

INTRODUCTION

Variation in naming in folk biological systems is so common, it almost goes without saying (Balée and Moore 1991; Berlin 1992: Chapter 5). However, the degree of variation is not applied consistently to each named plant or animal within the local flora and fauna. For example, the dataset upon which this paper is based shows that a plant species may be named by anywhere from one to twelve lexical variants within a single language group. So, why would some plants species contain less variation in naming, while others do not?

This thesis attempts to answer this question, in part, by examining the relationship between variation in plant medicinal use reports and lexical variation for a large set of ethnobotanical and ethnomedical data collected in the central highlands of Chiapas, Mexico by Elois Ann Berlin and Brent Berlin (1996). The analysis presents a means to categorize and quantify the extent of lexical variation and range of use reports both within and between two closely related Mayan languages, Tzeltal and Tzotzil. The relationship between medicinal plant use diversity and naming diversity is tested for three population groups – Tzeltal, Tzotzil, and the pooled data. The results detect a trend that for a selected set of 200 medicinal plant species, the more variation there is regarding a plant's medicinal use, the more the diversity of naming, both within and between closely related language groups.

CHAPTER 2

BACKGROUND

Nomenclature as a Guide to Classification

Names are the basic units of folk biological information. They are the labels used to identify and talk about plants and animals. Familiar examples of folk plant names in English today include red oak, sugar maple, dandelion, rose, and tomato plant. In addition to serving the basic purpose as labels, plant and animal names are part of a localized categorical system of information about the natural world and represent a large domain of shared cultural knowledge. The first step for description and analysis of any ethnobiological classification system is to elicit these names.

Analysis of plant and animal nomenclature largely pertains to regularities in the vocabulary and structure of names.¹ Of great interest to development of theory in ethnobiology is how these naming conventions apply to categorical or conceptual organization of the plants and animals they refer to. Through controlled study of the perceived relationships and groupings of organisms, ethnobiologists have been able to formulate a set of general empirical observations regarding the naming and classification of plants and animals by traditional societies. Berlin (1992:13-35) presents a concise historical overview and summary of this general set of principles.

Foremost in these observations is that certain consistencies exist in the names given to plants and animals which convey information about the perceived taxonomic relationships between species. This is seen in patterns such as life form (ex. bird, mammal, tree) and generic

taxa (ex. oak, bass) being labeled by primary names and subgeneric taxa being labeled with secondary names (ex. red oak, large-mouth bass) (Berlin 1992). Nomenclature has often been referred to as a “guide to folk taxonomic structure” (Berlin, et al. 1973b:216) and even provides other clues as to the cultural importance of species and historical development of systems of classification (ex. through differentiation) (Berlin 1972).

However, while nomenclature and classification are intricately linked, names alone are not sufficient for understanding the perceived relationships, categorical or otherwise, among plants and animals. For example, some primary names can at first appear to be complex secondary names (ex. sunflower, groundhog, tulip tree) and in some instances subgeneric taxa (folk species or varietals) can be labeled by primary names. The existence of *unnamed* conceptual groupings (ex. “covert taxa”) as well as named, but *uncategorized* taxa (ex. “ambiguous affiliations” and “residual categories”) are two of the extreme examples of how these two underlying structures – nomenclature and classification – diverge.

Response Variation in Ethnobiological Systems of Classification

Studies of ethnobotanical systems of classification certainly recognize the presence of considerable variation in the names assigned to plant species within the same society. In fact, the existence of so much variation has generated uncertainty from some, debate and criticism from others regarding methodological practices in the fields of ethnobiology and anthropology. Response variability in ethnobiological data is usually summarized or cut back in some way either at the time of collection or analysis (Medin and Atran 1999). The reasons for this are practical and methodological. Berlin, et al. (1974), in discussing the problem of informant variability and presentation of their data note:

It became clear very early in our research that it was impossible to speak literally of the “Tenejapa Tzeltal classification of plants.” In actuality, there are many such classifications, some idiosyncratic, others best described as microdialectical or ecological variants....Insofar as possible, we have attempted to stress those aspects of ethnobotanical knowledge that our data suggest are widely shared for the majority of speakers of Tenejapa Tzeltal. On the other hand, we also have made efforts to present in detail those aspects of plant knowledge that differ among informants and to provide...explanations as to why such differences exist. [58-9]

Similarly, Hays (1979), in his research on the ethnobotanical classification of the Ndumba peoples of the highlands of Papua New Guinea, compiled a list of 1,247 plant names, of which, only 970 were recognized by all his 10 adult informants. He states,

Many of these plant names are synonyms, some of which are alternative plant names that have diffused from neighboring speech communities with which there is frequent interaction, including intermarriage. Some synonymy is attributable to an extensive person name taboo system.... Also, sometimes individuals bestow ‘private names’ upon already-named plants for personal reasons, with some of these becoming more widely adopted. [256]

After careful attention to the “considerable” degree of variation in plant classification, Hays opts to deal only with information which is *shared* by his ten informants. His reason for this approach is to make the analysis “more useful for comparative studies, since published ethnobiological works overwhelmingly attend primarily to shared or composite models.”

Formulating models, however, does not preclude the inclusion of significant response diversity in ethnobotanical nomenclature. Yet, few standardized methods for collecting and analyzing variation in ethnobotanical nomenclature have been undertaken. Recently, however, there has been increasing interest in the field of ethnobiology on the importance of comprehensive, multi-site, and multi-language studies of variation in ethnobotanical knowledge (Balée and Moore 1991; Hunn 1999; Hunn 2001; López, et al. 1997; Medin and Atran 1999). Several earlier studies aimed at quantifying the “cultural consensus” or interinformant agreement are influential to the study of intracultural variation in ethnobotany, including the works of

Romney (1986; 1987), Boster (1986), and Garro (1986) with regard to culture theory and knowledge acquisition and transfer, and Stross (1973; 1975), Boster (1986), and Hays (1974) with regard to nomenclatural variation. Of direct relevance to the current analysis are the papers by Berlin, et al. (first published in 1969; 1973a) and Balée and Moore (1991), which explore plant name variation across historically related languages, and Berlin (1999) and Collins and Liukkonen (2002), which make within-language observations. Several recent papers have emphasized the oversight of comprehensive studies on intracultural, intergenerational knowledge variation, especially its loss over time, and demonstrated useful ways to incorporate its collection and analysis as a primary research concern (Ross 2002; Zent 2001).

There are many underlying reasons for informant response variability in naming that are specific and real linguistic and sociological factors and, in the domain of ethnobotany, characteristics of the plants themselves. Berlin (1992) summarizes the main types of response variation encountered in ethnobiology as either lexical or cognitive differences, although they are not mutually exclusive. Cognitive variation refers to the distribution of ethnobiological knowledge within a society due to differences in age, gender, education, occupation, intelligence, and other individual and group characteristics. Lexical variation, of particular concern here, are those differences that are observed in the names themselves.

With respect to the underlying causes for lexical variation in plant nomenclature, research seems to indicate that the more morphologically distinctive a plant species is (both size and “phylogenetic loneliness”), the more likely the plant will be named and the greater the likelihood that the name assigned to that plant will be unique (Hunn 1999; Berlin, et al. 1974). The same observation appears to be true for culturally important plant species – people tend to have greater consensus on the names for plants that are cultivated or intensively managed (Balée and Moore

1991; Berlin 1992; Berlin, et al. 1973a; Berlin, et al. 1974; Boster 1986). Although not yet fully explored, some ecological factors can also potentially influence the perceptual salience of a plant, and consequently, lexical variation, notably species abundance and geographical distribution (Berlin 1992; Berlin, et al. 1974; Boster 1986). Historical linguistic factors such as borrowing and linguistic properties of the words themselves may also influence name retention and change (Balée and Moore 1991; Berlin 1972; Berlin, et al. 1973a; Berlin, et al. 1974; Campbell 1998; Stross 1975).

Change and Loss of Ethnobotanical Knowledge

In linguistics, biology, and, by association, ethnobiology, individual variation is the origin of change, which includes loss of information as well (Boster 1986; Garro 1986; Pelto and Pelto 1975; Zent 1999). The current analysis takes advantage of the existing wealth of ethnobotanical data from Berlin and Berlin's (1996) research to demonstrate one method for analyzing individual lexical variation at a single point in time but may also permit insight into the historical changes in ethnobotanical knowledge over time – why a plant's name may persist or change over hundreds of years. Historical linguistics demonstrates that through careful use of the comparative method, it is possible to understand the diachronic processes of language change through the comparison of words (cognates) in related languages (Campbell 1998). By careful comparison of plant lexemes across languages, Berlin, et al. (1973a) and Balée and Moore (1991) are able to infer that the inter-language patterns in their ethnobotanical data indicate historical retention since the time of proto-Tzeltalan and proto-Tupi-Guarani, respectively. The current analysis similarly discusses some of the historical inferences that may be made from the data.

This study also addresses the current need for further comprehensive research into traditional knowledge of the environment due to the accelerated socioeconomic, cultural, and environmental changes in traditional and small-scale agricultural societies. The study of language and knowledge loss is as equally urgent an issue as our attention on biodiversity issues (Maffi 2001b). The interconnectedness of these issues is perhaps best articulated in the area of ethnobiological knowledge: The loss of knowledge about living things is a consequence of species and habitat loss and, conversely, loss of knowledge may contribute to species endangerment and language loss itself. In relation to Chiapas, for example, Maffi (2001a) remarks anecdotally on the rapid degradation of traditional medical knowledge in the adult generation in 1996:

It could not be that they had not *yet* acquired the traditional medical knowledge. Could it be that they had not acquired it *at all*? ...[The two men] were trying to dredge up and piece together scattered fragments of latent ethnomedical knowledge-knowledge perhaps only imperfectly learned, never concretely used, and now almost forgotten. I heard them question each other: “What’s its name, the grasshopper thing?” The “grasshopper thing”: *yakan k’ulub wamal* ‘grasshopper leg herb’ (*Verbena litoralis*), one of the commonest diarrhea remedies in the Highlands. They could hardly remember its name, let alone master its use. [2-3]

The loss of language has direct implications for loss of knowledge about and management of the natural environment, but likely too has deeper cultural consequences. As Hill (2001) reports in her study of the biosystematic lexicon of the Tohono O’odham language in Southern Arizona- the loss of biological vocabulary may compromise more than just the lexicon. For a subsample of mostly elderly informants, Hill found that informants who could remember the names for plants and animals often made additional comments about the natural history of the organism, personal experiences related to it, or reacted emotionally (with disgust or affection) while being shown pictures of local plants and animals. Hill notes, “when names are

lost, people lose not only encyclopedic nature knowledge; they even experience weakening of access to their own feelings and life histories.”

This emphasis linking cultural and environmental research promises to be an important and productive aspect of ecological and applied anthropology and conservation in the future. In addition, the study of lexical variation in ethnobotanical nomenclature can help to improve our data collection methods in ethnobiology, our understanding of the distribution of plant knowledge within a society, and our ability to continue to build theory regarding ethnobiological classification.

CHAPTER 3

CHIAPAS HIGHLANDS: SETTING AND LANGUAGE

Chiapas is the southernmost state in the Mexican peninsula, bordered by Guatemala to the east and the Pacific Ocean to the southwest (Figure 1). The central highland region of Chiapas has an estimated population of almost 600,000 (INEGI 2000). The sector of the central highland region included in this study covers an area approximately 3,300 km² (1,200 mi²) divided into 14 Tzeltal and Tzotzil municipalities (Figure 2)^{2,3}. Figure 3 shows the population of each of the municipalities relative to each other. Approximately 295,000 people reside in these 14 central highland municipalities.

According to the 2000 Mexican National Census, 7.2% of the country's population speaks an indigenous language, 24.7% of whom reside in the state of Chiapas. Ninety-eight percent (98%) of the population within the study area speak an indigenous language, 84.7% of whom (over the age of 5) speak either Tzeltal or Tzotzil (INEGI 2000). Nationally, there are 297,561 speakers of Tzotzil and 284,826 Tzeltal speakers, 40.6% and 41.4% of whom, respectively, are monolingual. For both Tzotzil and Tzeltal, a greater proportion of women are monolingual – approximately 50% of women and 30% of men.

Tzeltal and Tzotzil are sister languages in the Mayan language family, descended from proto-Tzeltalan (Berlin, et al. 1974; Campbell 1998; Kaufman 1971). Figure 4 displays the relationship of Tzeltal and Tzotzil to the other closely related modern-day Mayan languages and language families. It is estimated that Tzeltal and Tzotzil began to divide about 1,200 years ago. Historically, Tzeltal is spoken in six of the central highland municipalities. Kaufman (1971)

groups these municipalities into three separate dialects: Aguacatenango and Amatenango as “Southern Tzeltal”, Tenejapa and Cancuc as “West Central Tzeltal”, and Chanal and Oxchuc as “East Central Tzeltal”. Tzotzil is spoken in eight of the 14 municipalities, divided into the following dialects: Chalchihuitán in “Northern Tzotzil”, Larráinzar classified in “Western Tzotzil”, Chenalhó, Mitonic, Chamula, and Zinacantán as “Central Tzotzil”, Huixtán within “Southern Tzotzil”, and Pantelhó is unclassified (Hopkins 1970, cited in Berlin, et al. 1974). For reasons discussed in the Methods section, the current study includes data from only nine of the fourteen municipalities: the five Tzotzil-speaking municipalities of Chamula, Larráinzar, Chenalhó, Mitonic, and Huixtán and the four Tzeltal-speaking municipalities of Aguacatenango, Cancuc, Oxchuc, and Tenejapa. These municipalities represent approximately 78% of the 14 central highland municipalities in terms of population and 58% in terms of area.

Although cultural identities are strongly linked to municipal boundaries, evidenced by distinct clothing styles and language differences, the region as a whole has a considerable amount of cultural exchange and similarities. There is relatively close contact between Tzeltal- and Tzotzil-speakers and frequent contact with the Spanish-speaking Ladino population living in the area. Intermunicipality migration, marriage, and exchange are not now uncommon in the region. Berlin, et al. (1974:7-9) and Berlin and Berlin (1996:28) note that a significant minority of the population in many areas is bilingual Tzeltal-Tzotzil, although figures are difficult to estimate. According to the most recent census figures, in the historically Tzotzil-speaking municipalities of Pantelhó and Huixtán, 50% and 33% of their respective populations are now Tzeltal-speaking. State education and literacy programs in Spanish have also increased throughout the highlands in recent years (Berlin and Berlin 1996:6). According to the 2000

Mexican Census, 41.3% of the area's population over the age of 5 who speak Tzeltal or Tzotzil also speaks Spanish.

These and other sociolinguistic factors together with ecological features of the region are likely to affect patterns of knowledge transmission, language change, demographic change, and economic development, which, in turn, impact ethnobotanical knowledge. This large area contains a diverse composition of microclimates and vegetation types due to its mountainous terrain and altitudinal range from 500 to 2500 m. Because of this, there are local and regional differences in vegetation as well as agricultural zones and livelihoods, often within the same municipality⁴ (Berlin, et al. 1974; Berlin and Berlin 1996; Breedlove and Laughlin 2000; Maffi 1999). Population density, access to infrastructure, natural boundaries of the region, and plant composition may all affect access to and communication about plant medicines, but also access to Western medicines and clinics.

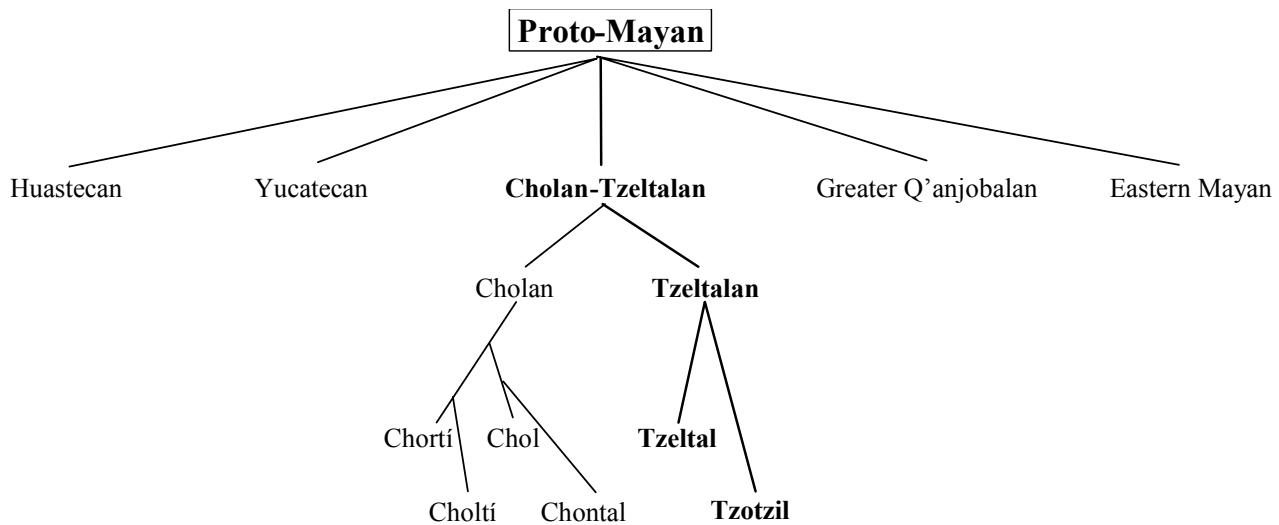

Figure 4: Tzeltal and Tzotzil languages in relation to major Mayan subgroupings. Modified from Campbell (1998:171).

CHAPTER 4

METHODS

Dataset

The dataset drawn upon for this analysis comes from an existing dataset created by Brent Berlin and Elois Ann Berlin during their field research for Medical Ethnobiology of the Highland Maya of Chiapas, Mexico: the Gastrointestinal Diseases (1996). The complete dataset contains a total of over 24,400 plant name responses for 200 botanical species (two of which have only been determined to genus). These 200 species comprise the most frequently collected, and by implication the most common, medicinal plants of the approximately 1650 species collected and catalogued by Berlin and Berlin during their fieldwork from 1987-1990. Each species was collected on six or more occasions in several municipalities. An experimental herbarium was employed for the standardized collection of lexical and medicinal information about each species. The herbarium consisted of pressed botanical specimens secured within clear plastic sheets and placed in a 3-ring binder. Informants were shown the same set of 200 specimens and asked to provide the name and information regarding medicinal use for each specimen (Berlin and Berlin 1996). This ensured that all informants identified the same individual specimen. Interviewers recorded one name and up to four medicinal uses for each plant specimen. For details about the dataset and methods used in collection, refer to Berlin and Berlin (1996).

For this paper, I selected a subset of 12,072 records from nine of the fourteen municipalities, which contained the cleanest and most reliable data available at the time of analysis. This data includes responses from 7-10 knowledgeable informants from each of the municipalities. The average number of responses per plant species is 27 from the Tzotzil

localities and 33 from the Tzeltal municipalities. Respondents are 60% male for Tzotzil and 54% male for Tzeltal, on average. Where possible, response data from more of the fourteen central highland municipalities was incorporated into the analysis. This resulted in a few extra responses for four species, including 33 additional responses from all five additional municipalities for one species; one response from Chalchihuixtán for a second species, one from Chanal for a third, and one from Zinacantán for a fourth. Approximately 12,000 name responses and 15,000 medicinal use responses are included in the current dataset.

Medicinal Use Data

The use responses are coded into classes of illnesses and these categories are used to calculate medicinal use agreement. This variable, developed by Berlin and Berlin (1996), groups related health conditions into what they refer to as “condition classes.” The top-10 ranked condition classes for both languages, in order of frequency from most reported to least, include gastrointestinal illnesses, respiratory illnesses, dermatological problems, accidents, fevers, musculoskeletal pains, eye problems, headache, mouth/dental problems, and conditions characterized with non-natural etiology. The main benefit of using illness classes rather than specific illnesses is that the more inclusive variable is likely to capture the highest level of general consensus regarding a plant’s sphere of medicinal application, such as for gastrointestinal problems generally rather than specifically for diarrhea, stomach pain, or worms. This is important if, for example, one informant reports all three of the above uses but another only reports stomach pain. Where an informant reported two or three different illness uses belonging to the same illness class, as in the above example for gastrointestinal diseases, the use report is only counted one time per informant, not as 3 responses.

Plant Name Data

Trained Mayan collaborators, all native speakers of Tzeltal and Tzotzil, collected plant name data. Although this lead to a fairly high accuracy of transcription, errors are common in the data. Errors in transcription include missing or misplaced glottal stops, abbreviations of words, contraction of terms, upper-case “I” being recorded as lower-case “L”, “a” being recorded as “o”, interchanging the Spanish “b” with “v”, “j” and glottal stops being interchanged, or “s” with “x”, among others.

To correct these errors and, more importantly, to control for differences in dialect and language, the names are standardized. These standardized names are derived through term-by-term comparisons of sound correspondences between words, drawing heavily upon published dictionaries and previous work in Tzeltal and Tzotzil plant nomenclature (Berlin, et al. 1973a; Berlin, et al. 1974; Berlin and Berlin 1996; Laughlin 1975; Laughlin and Haviland 1988) and in keeping with observations of the response patterns in the data.

Lexical variation, as Berlin (1992) points out, differs significantly in quality. Most lexical variation is simple phonological variation – minor differences in sound. For the purpose of this analysis – to identify similarities and dissimilarities in nomenclature – only true lexical variation is considered. True lexical variants are distinctive terms, which are not derived from the same term. When a single biological species is recognized by two or more distinct folk names, these names are considered synonyms – two words having a similar meaning. Under a few circumstances described below, these synonyms are coded as *similar* names for the purpose of this analysis based on clear semantic similarities. An example of true lexical variation is

illustrated by the following list of names given for one of the botanical species in the dataset,

Lantana camara:

Tzotzil: ***ch'il te' vet*** ‘fox rib tree’, ***nekeb vet*** ‘fox shoulder’, ***bik'tal ch'ilvet*** ‘small fox rib’, and ***tzajal nich vomol*** ‘red flower herb’ and

Tzeltal: ***ch'il ch'il wajch'*** ‘*ch'il ch'il* twig’, ***tzajal ch'ili wet*** ‘red fox rib’, ***yaxal nich wamal*** ‘yellow flower herb’, ***bak te' pox*** ‘bone tree medicine’, and ***ch'aj bakal wamal*** ‘bitter bone herb’.

Simple phonological variation, or changes in sound, account for the greater majority of variation in the name data and are not considered significant lexical differences for this analysis. An example of this type of variation can be seen in the Tzeltal and Tzotzil names also given for

Lantana camara:

Tzotzil: ***ch'ili vet jomol*** ‘fox rib herb’, ***ch'il vet vomol*** ‘fox rib herb’, ***ch'il te' vet*** ‘fox rib tree’, and ***ch'il vet*** ‘fox rib’ and

Tzeltal: ***ch'il wet wamal*** ‘fox rib herb’, ***ch'ili wet wamal*** ‘fox rib herb’, ***ch'ili wet*** ‘fox rib’, and ***ch'il wet*** ‘fox rib’, in addition to the phonological variants, ***ch'il ch'il wajch'*** ‘*ch'il ch'il* twig’ and ***ch'il ch'il wach'*** ‘*ch'il ch'il* twig’.

Other examples of phonological variation in the data include contraction of terms, such as ***pojowil*** and ***pojow*** or ***muitaj*** and ***muil itaj***, vowel or consonant shifts such as ***moen*** and ***moem***, or ***moy*** and ***may***, and deletions such as those mentioned above. Oftentimes, such terms are cognates inherited from a common word in the proto-language.

Names judged as similar are transformed into a single notational form for the purpose of quantifying significant name variation. Notational forms are summaries of the language and dialectical differences that occur for plant name variants in the data. These notational forms are written into a single code name and serve as the raw data for frequency counts of names. The notational forms of these standardized names and sets of similar names for each species by

language are included in Appendix A. They are useful for the present analysis of similarity, but not for linguistic accuracy.

In the notational forms, synonymous terms for ‘herb’ are written with a tilde (~). Vowels, consonants, or terms occurring interchangeably in name responses for a particular plant are separated by a backslash (/). A term that is present in some names but absent in others is included within parentheses (()). Below are several examples of how response variants are standardized and cited for three botanical referents:

Lippia chiapensis:

pech jo nich te', *pech jol nich te*', *pexol nich te*', *pexko nich te*', *pixko nich te*', *pixo nich te*', *pixol nich te*' ‘hat-flower tree’ and *pixko nich, pech' jo nich, pexol nich, pixol nich* ‘hat-flower’ are coded by the notational form “*pixko/p{e/i}xol/pechjo(l) nich (te')*”

Senna foetidissima:

chenek' mut ‘bird’s bean’, *chenek' mut te*’ ‘bird’s bean tree’, and *chenek' mut wamal, chenek mut wamal, chenek' atinel mut wamal* ‘bird’s bean herb’ are coded as “*chenek' mut (te')/~/*”;

Zanthosylum foliolosum:

elmonex ch'ix, elmunex chix, elmunex ch'ix, eremux ch'ix, ermunix ch'ix, eremunex ch'ix, eremunix ch'ix ‘spiny lemon’, *elemonex ch'ixte*’ ‘spiny lemon tree’, and *elmonex ch'ix wamal* ‘spiny lemon herb’ are coded as “*el(e)monex/er(e)monix ch'ix (te')/~/*”.

Other name differences that are not considered theoretically meaningful for this analysis are common plant name elements such as life forms (tree, herb, grass) and other attributives such as plant parts (leaf, flower) when used interchangeably or sporadically in reference to the *same* species. The frequent use of plant parts such as leaf, flower, or stem in the name data may be a result of the stimuli – pressed plant specimens of stems with leaves and flowers – in some cases. Collins and Liukkomen (2002:622) similarly observe in their analysis of lexical variation for the Q’eqchi’ Maya of Guatemala that, with the exception of the term for ‘tree’, free variation of plant part and life form terms for “leaf, thorn, herb-weed, grass, vine, fern, sedge, and tall grass” recurs with frequency in compound lexemes. Therefore, complex names (containing two or more

terms, not including life form) that would be identical if not for differences in life form attributes or the use of ‘flower’ are grouped together under a single index name.

Additionally, where present, modifying adjective morphemes in the name, commonly, color or size attributes, are separated out from the compound names to create a basic, or core, plant term. Plant names are considered similar regardless of differences in color or size attributives. Color and size attributes are the most commonly used modifiers in the data, (occurring in 16% of name responses). The following is a real example showing some phonological variation as well as different color and size attributives standardized for the species, *Lantana hispida*:

bik'tal ch'ili vet ‘small fox rib’, *ch'il vet vomol* ‘fox rib herb’, *ch'ilivet* ‘fox rib’, *ikal ch'ilwet wamal* ‘black fox rib herb’ *ijkal ch'iliwet*, *ijkal ch'il wet* ‘black fox rib’, *mukil ch'il te' vet* ‘big fox rib’, *sakil ch'il vet* ‘white fox rib’, *tzajal ch'il vet*, *tzajal ch'il wet*, *tzajal chiliwet* ‘red fox rib’, *tzajal ch'il wet wamal* ‘red fox rib herb’ are all noted by the core name “*ch'il(i)(te')* v/wet ~”.

Simple plant names, on the other hand, including only a color term + ‘flower’, with or without life form labels, retain the use of both color and ‘flower’ morphemes. In this case, without further data, it is assumed that color + ‘flower’ represents a legitimate name, not just a descriptive phrase. For example, *k'anal nich ak* ‘yellow flower grass’ and *k'anal ak wamal* ‘yellow grass herb’ are coded as a similar name, “*k'anal (nich) ak ~*”, in reference to the species *Pinaropappus spathulatus*. This data cleaning and matching of plant names resulted in the reduction of responses from over 3,400 unique name responses to 1,459 standardized plant name sets.

Finally, the standardized cognate and noncognate names are compared by species for overall similarities in vocabulary and meaning using rules similar to Balée and Moore’s method for analyzing plant lexical variation between languages (1991). If the principal morphemes in the

plant name, whether descriptive (“metaphorical”) or semantically opaque (“literal”), are cognates or otherwise similar in sound and meaning, the names are considered similar regardless of the other morphemes occurring in the name. The other morphemes most commonly include different life form terms and plant part terms (such as flower, leaf, root, stem), words for animals (occurring in about 13% of name responses), ‘wild/devil’s’ *pukuj*, ‘foreign/Spanish’ *kaxlan*, ‘elder sister’ *vixil*, ‘ground/earth’ *lumil*, ‘ancestor’s/ancient’ *antivo*, and ‘medicine’ *pox/poxil* (all together occurring in about 3% of name responses). For example, for the species *Baccharis serraefolia*,

mero varaxik’ ‘true winged vara’, *var(a)/vala(k) xik*’ ~ ‘winged vara’, and *vixil valak xik*’ ‘elder sister winged valkak’ are noted by the similar index name “-*var(a)/vala(k) xik*’-”.

It is interesting to note that these attributive terms are common constituents of unproductive plant names formed by analogy and there is some evidence that their use indicates the species is not of primary cultural importance (Balée 1989; Berlin, et al. 1974:38-39), is useful only as a medicine (Berlin, et al. 1974:38), or is not a traditional cultigen (Balée 1989:14). All of these characteristics have been affiliated with high degrees of lexical variation in these prior studies.

The only other non-cognate terms for which lexical differences are ignored are synonyms for ‘diarrhea’ (*ja' ch'ut/tza'nel*) given for *Lepechinia schiedeana*, the free variation of ‘food of the caterpillar sp.’ with ‘caterpillar sp. herb’, terms for ‘leg’ (*akan, ok*) and ‘claw’ (*yich'ak*) in the name ‘chicken leg (tree/herb)’ given for *Oreopanax xalapensis* and bird terms for ‘chicken’ (*mut*) and ‘turkey’ (*tuluk*) in the complex name ‘chicken/turkey feces tree’ given for *Conostegia xalapensis*. This treatment of the data provided a thorough assessment of concrete differences and similarities in naming and further reduced the overall response list from 1,459 to 1,124 Tzeltal and Tzotzil index names, or an average of 5.6 names per plant.

Borrowed terms were not excluded from the analysis. Spanish is the most evident and common source of borrowings. One thousand sixty-eight (1,068; 8.8% of the total) responses given for 85 plant species are confirmed plant name borrowings from Spanish or contain a Spanish loan as a major constituent in the name. Some of these have their origins in old colonial Spanish. Three standardized names, representing 113 individual responses, are also suspected of being Spanish loans, for a total of 1,181 responses (9.8%) of likely Spanish origin. An additional 115 responses contain only a Spanish-borrowed attributive: *antivo* ‘old, ancestor’s’, *kaxlan* ‘Spanish’, or *simaron* ‘wild’.

Analytical Method

The unit of analysis for this study is the botanical species, which serves as a reference by which to compare multiple identifications. In order to test the hypothesis regarding the relationship between plant naming and medicinal use, two index measures are calculated for each botanical referent indicating the degree of consensus on name and use. Thus, each of the 200 species is represented by one name value and one use value. Name and use consensus are then described and correlated across the 200 plants using their respective index scores.

To measure plant name and use consensus within and between each language group, the Shannon-Weiner diversity index is used (Siegel 1956; Weiner 1948)⁶. The Shannon-Weiner index is widely used as a measure of biological diversity in the field of ecology, but is a useful and simple tool for measuring the diversity of any set of categories for a given domain. In this case, the categories are plant names or medicinal uses and the unit of analysis is the plant itself. The formula for calculating the Shannon Index (H_1) is

$$H_1 = -\sum p_i \log_2 p_i,$$

where p_i is the proportion of responses for a given name or use for each plant. The Shannon Index takes into account both the magnitude of response frequencies and the number of response categories, in other words, the *response diversity* for each plant. This method differs from those employed previously by Berlin et al. (1973a) and Balée and Moore (1991), which made paired comparisons of only single terms from each language and is very similar to that used independently by Collins and Liukkonen (2002) in measuring name variation. Rather than discounting anomalous responses in the data, this method preserves all the detail and integrity of the original data and thus, gives a truer indication of the diversity of opinions occurring in the sample population. Values can range from zero, for plants with only one unanimous category reported by all informants ($1 * \log_2(1) = 0$), to ever-increasing values for plants with multiple response categories, each given by only one or two informants.

The Shannon indices for each plant are calculated for each language separately and the pooled language data. The variables are then described statistically and compared using paired t-tests and correlation analysis. Since missing data is an empty category, including them in the calculations would treat “missing” as legitimate name category. Therefore, missing responses are not included in the either the frequency counts or the sample N.

CHAPTER 5

RESULTS

The medicinal uses for plants in the sample herbarium reported by Tzeltal and Tzotzil municipalities are listed in Table 1. Reports of medicinal plant uses are very similar for both groups. The list reflects a concentration of naturalistic conditions and ailments common to people living in rural areas under similar socio-economic conditions (Berlin and Berlin 1996). For example, the top three ranked illness classes in terms of response frequency are gastrointestinal, respiratory, and dermatological conditions, accounting for 48.7% of responses from Tzeltal and 49.0% for Tzotzil. Ankli, et al. (1999), utilizing Berlin and Berlin's (*ibid.*) illness categorizations for their study of medicinal plant use for Yucatec Mayan communities, note these same top three condition classes for their study sample. Interestingly, although the correspondence of plant use *categories* is high between the Tzeltal and Tzotzil data groups, the rank correlation between the use diversity indices for all 200 species is weak ($\rho = .178$, $p < 0.05$). In other words, the two language groups rank the plants quite differently according to the use diversity index.

Table 2 and Table 3 display some descriptive statistics for the index values of use and naming diversity. In general, the use diversity values are considerably positively skewed, indicating that there is a greater frequency of plants with high use diversity reports. A t-test of the difference between the mean values for medicinal use diversity for Tzeltal and Tzotzil shows there is a significant difference in the average amount of response diversity between the two language groups (Table 4). Tzotzil has significantly more diversity of uses reported, on average,

than Tzeltal. However, there is not a significant difference in the means for naming diversity between the two languages ($p=0.353$) and the name variable is more evenly distributed with respect to the mean. In addition, there is somewhat greater correlation between the ranking of plants for name diversity than for use diversity for the two languages ($\rho=0.365$, $p<0.01$). A test of the differences in the sample means between use diversity and name diversity reveals that use diversity is significantly higher for all three data analysis groups (Table 5).

The data also indicate that there is a higher level of variation in use reports for the pooled data. The minimum value of use diversity for the pooled data is much higher than those of the individual languages ($H_1=1.20$ compared to 0.00 for Tzeltal and 0.69 for Tzotzil). In addition, the differences in the mean values for use diversity for the pooled and unpooled language groups are significant (Tzeltal $p<0.01$, Tzotzil $p<0.02$; 2-tailed t-test, equal variances assumed). In other words, both the degree of medicinal use diversity and naming diversity are *higher* for the pooled Tzeltal-Tzotzil data. This result corroborates the expectation that the within-group consensus is greater than the between-group consensus.

In order to test the association between use and name diversity for the sample herbarium, both a Spearman's rank correlation and Pearson correlation are calculated. The results can be viewed in Table 6. For all three groups of data, the correlation is positive and significant ($p<0.01$), but weak. Stated in terms of consensus: as consensus on a single medicinal use increases, consensus on what the plant is called also tends to increase. Medicinal use agreement alone, based on the R^2 for the correlations, explains only between 4-6% of the variation in naming for the sample.

Figure 5, Figure 6, and Figure 7 show the graphs for medicinal use diversity by diversity of plant name and display the least-squares regression lines for Tzeltal, Tzotzil, and the pooled

data sets. Observing the distribution of plant species in the graphs, the results for all three analysis groups show a large clustering of species with high use diversity and name diversity, while only a few species have both low use and low name diversity.

Table 1: Frequencies of illness responses grouped into condition classes

Illness Class	Tzeltal	Percent Tzeltal	Tzotzil	Percent Tzotzil	Row Total	Percent Total
Gastrointestinal	1750	24.9	1899	23.8	3649	24.3

CHAPTER 6

DISCUSSION

That use diversity is significantly greater, on average, than name diversity may in part be an artifact of the data collection methods. About twenty percent of the total number of use responses are reports of more than one use, which could have produced a slightly greater number of use categories for some plants. Keeping this in mind, the higher rank correlation of name diversity between the two languages appears to indicate that informants have greater consensus on the names for the plants than they do on a single, particular use for each plant. The result fits well with the expectation that agreement on the name of a plant can exist *independent of* knowledge about its medicinal use. High name consensus may be a consequence of another salient characteristic of the plants other than medicinal importance, as stated earlier. The higher degree of use diversity also corresponds with the expectation that for concrete domains, such as plant species, more variation will exist in describing its attributes than in its identification (Boster 1986:434).

The overall distribution of the data shows that there are a very limited number of species with low use and name diversity and a much greater number with high use and name diversity. Therefore, it appears to be these species that are driving the observed correlations. It would be interesting to look more closely at these particular species to see why this may be the case. Appendix B lists the overall ranks for each plant species as a weighted average of their name and use ranks and provides their Shannon index values.

For a relatively large sample of plants and informants, the results suggest that there is an overall positive relationship between medicinal use diversity and plant name variation, both within Tzeltal and Tzotzil and between these two closely related languages. Therefore, similar to the comparative ethnobotanical research of Berlin, et al. (1973a) and Balée and Moore (1991) on degree of plant management, the present linguistic evidence suggests that medicinal use agreement may also affect agreement on name by encouraging the retention of a name in related languages or through name borrowing. The results statistically confirm a speculative look at the data by Berlin (1999), which examined counts of the number of names and number of uses for a select few species within each language group separately. The findings are interesting in light of Zent's (2001) study of ethnobotanical knowledge among the Piaroa in Venezuela. Zent found that plant-naming competence was significantly positively correlated with use-value competence for forest tree species for medicinal as well as a variety of other uses.

While the results presented are suggestive of a pattern regarding the affect of use consensus on plant naming, they also indicate that medicinal use contributes relatively little to the overall lexical variation in the ethnobotanical system of classification. The low R-squared value of the correlation indicates that only a small amount of variation in naming is attributable to the degree of medicinal use variation. This result reemphasizes the observation that there are many variables other than medicinal use affecting the name consensus. Further research is required to accurately predict what those variables are. Past research has presented convincing evidence demonstrating that the degree of plant management – from cultivated to non-cultivated – is strongly correlated with the nomenclatural characteristics of the plant names and lexical retention (esp. Berlin et al. 1973 and Balée and Moore 1991); however, these categories of plant

importance are not clearly distinguished from the ecological factors inherent in their definitions.

In addition, the overall response variation was not taken into account in these studies.

Some of the factors specifically related to the plants themselves that are missing from the current analysis and likely to be contributing to true lexical diversity include cultural salience other than medicinal, plant distribution, morphological distinctiveness, access to plants as influenced by local geography and infrastructure of the region, the native origin of the plant, and the linguistic qualities of the plant terms. In order to better understand the multiple contributing factors to variation in naming, a broad, unbiased plant sample, with data on some or all of these attributes is needed. Perceptual salience should theoretically be more important than cultural factors in determining which plants are named and, as a corollary, lexical variation (cf. Berlin 1992; Hunn 1976; 1999); however, mounting evidence points to the strong influence of cultural factors on classification systems (cf. Medin and Atran 1999; Medin, et al. 1997). Although this analysis does not examine the distribution of informant knowledge, the analysis would be greatly enriched by and lends itself to further study of the socio-demographic factors at work. An analysis of interinformant agreement would indicate whether there are clusters of informants who tend to agree more with each other.

The theory of cultural consensus is appropriate for interpreting shared knowledge of medicinal plants across a broad geographical and linguistic area such as highland Chiapas. Since the plant species included in the survey are a subset of common medicinal plants in the region, they are plants that would be seen by most of the population and probably on a frequent basis. They may also be the plants more likely to be used or tested as remedies. On the other hand, the relatively high number of plants with high use *and* high naming diversity seems to indicate, as does Boster's observation regarding Aguaruna names for manioc, "...that there is more to culture

than consensus, that in some situations the deviations from the cultural consensus may constitute a significant portion of the pattern of agreement between individuals.”

Inasmuch as medicinal *importance* might be inferred from low response variation, the data seems to indicate that the more important a plant is as a medicine, the more widespread the knowledge about the specific medicinal use, and the more agreement there is regarding its name. Taking the argument a step further, Berlin (1999) speculates that agreement on name is likely to be driven by the pharmacological *effectiveness* of the plant as a medicine, a speculation currently being tested through his current work on the medical ethnobiology of Chiapas (Berlin and Berlin 1996). However, in order to directly test the relationship between *perceived* importance of the plants as medicines, further data would need to be collected to rank plants for use value. There is a general need for comprehensive data collection incorporating better methods for quantifying the relative importance of plants and to determine how effective consensus is as a measure of importance.

Although similarities in borrowed terms do not indicate retention of terms from the proto-language, their presence does not diminish the value of conclusions regarding overall naming agreement and, given the small proportion of borrowed terms in the data, probably do not significantly impact conclusions regarding language retention. As stated earlier in the paper, approximately 10% of name responses are likely Spanish borrowings. Compare this figure to the 90 (19%) nonnative terms out of 471 generic names in the Tenejapa Tzeltal plant inventory by Berlin, Breedlove, and Raven (1974). The Tenejapa Tzeltal inventory is believed to be representative of the generic taxa recognized locally, not including all alternative lexical expressions (*ibid*:153). The lower proportion of borrowed terms in the current lexical data may be due to a smaller number of cultivated plants in the experimental herbarium. In addition, Hunn

(2001:128), comparing modern Zapotec ethnobotanical terms with historical records from the year 1578, reports an interesting preliminary finding suggesting that Spanish borrowings show long-term stability in the ethnobotanical lexicon and do not affect ethnobotanical knowledge or linguistic context. Nevertheless, interpretations of the present results' relation to lexical inheritance should be taken as merely suggestive. In order to distinguish between borrowed and inherited plant names, all loan words would need to be removed from the data or their influence otherwise accounted for in the analysis. It would be interesting to analyze the difference between the Old Spanish loans, recent borrowings, and native terms.

Finally, there may be issues with the data collection and aspects of the analytical methods chosen which are obscuring the relationship. The use of pressed herbarium specimens, while enabling standardization of data collection, may have been inadequate stimuli for some informants – resulting in vague responses or no response, or making identification of only certain plants difficult for all informants. Also, the plant data used in this study is derived from a collection targeted at medicinal plants, so it is unclear how representative it is of plants in the region. In addition, as only half of the original dataset was used in the current analysis, the addition of the rest of the dataset would strengthen the validity of the analysis and results.

Another possible issue affecting the findings is the treatment of the plant terminology. Some of the names included in the data may turn out to be descriptive phrases and not valid plant names. There is some general indication that this may be the case, as the most frequent plant name responses indicate: *yax(al) ~/yaxal nich* ~ ‘green herb/green flower herb’ (approximately 4% of all name responses), *k'an(al) nich(im)/k'anal te'* ~ ‘yellow flower/yellow tree/herb’ (approximately 4% of name responses), and *tz'ajal nich(im)* ‘red flower’ (approximately 2% of name responses). In addition, in the current treatment of the data, 47 plant names ignored the use

of different life-form constituents in the name, such as ‘tree’ and ‘herb’. In many of these cases, the variant life-form attributive occurred at such a low relative frequency as to be anomalous. However, in the remaining cases, further data could prove these similar names to be distinct synonyms.

The use diversity index may also be somewhat problematic as a measure since, as stated earlier, it does not take multiple response overlap into consideration. Use diversity, while implying one type of consensus – consensus around a single category of use – it does not capture and give weight to instances of plants with more than one legitimate use. Moreover, the Shannon index increases as the number of categories (uses) increases, even though informant’s opinions may overlap partially or completely on several categories. For example, the index value for a plant with a single use category would show greater agreement (i.e. no diversity) than a plant with two use categories, complete consensus on one category, and partial consensus on the second.

CHAPTER 7

CONCLUSION

A considerable amount of variation exists in the names given for a plant species, even with a sample of knowledgeable informants. However, this variation is not applied consistently across the sample of plants and can be measured effectively in order to better understand the patterns within the variation. This analysis presented one means to begin to measure and analyze response variation in ethnobotanical knowledge and use it to test hypotheses regarding the patterns of knowledge about plants and knowledge change. Through comprehensive, multi-site data collection and close examination of the lexical variation in ethnobotanical knowledge we are able to gain insights into “how the system works” (Pelto and Pelto 1975) and under what conditions it does not. Furthermore, analysis of true lexical variation within and amongst closely related languages may better reveal how ethnobotanical systems of classification change and may be impacted by changing socioeconomic patterns, acculturation, and changes in the environment – all factors which significantly affect local opportunities to talk about, experiment with, and observe the plants around them.

¹ For detailed descriptions of the folk botanical nomenclature and classification for Tzeltal- and Tzotzil-speaking peoples, refer to the work of Brent Berlin and his colleagues (1973; 1974) and Brian Stross (1973) for Tzeltal and the work of Dennis Breedlove and Robert Laughlin (1993; 2000) for Tzotzil.

² Based on area analysis of the scaled maps.

³ Aguacatenango is actually a Tzeltal township located within the Tzotzil municipality of Venustiano Carranza (Berlin and Berlin 1996:35-36). Population estimates for Aguacatenango township were derived from the Mexican 2000 census figures for the Tzeltal-speaking population of Venustiano Carranza.

⁴ For an interesting discussion of “hot” and “cold” zones and the origin of this terminology, see Luisa Maffi (1999).

⁵ Maps of study area created by author in ArcView GIS 3.1. Digitized from 1:50,000 scaled topographic maps published by the Dirección General de Geografía, Mexico, D.F., 1965.

⁶ Originally developed in the field of communications theory. I am grateful to my professor, Theodore Gragson, for first suggesting it to me.
